You start in the tutorial level, which mainly teaches how the game works. After setting the controller layout, you can enter the level editor.

To get to the level editor, press and hold X on the GameCube controller and select Access Level Editor from the selection menu.

The top screen shows the current level, with its' camera view.

Move with the Wii remote controller and the character rotates with you. Press the R shoulder button to enter combat.

The bottom screen shows your stats. Press X to get to the pause menu.

If you want to select two different controllers (for example, to play the level with your Wii remote and a GameCube controller), follow the local instructions.

Currently, a switch toggles its output cycle by using an input clock signal. When the switch is off, the incoming current from a power source is received at the input of the switch. When the switch is on, the current is blocked. There is no current or voltage drop occurring in the circuit. However, with increased processing speeds in power converters, such as motor-driven DC-DC power converters (MDDCP), there is current change immediately when the switch cycles, which results in a voltage drop or spike. Such current change is largest when the switch is switching to be off. The voltage ripple can be as large as many volts. The ripple voltage can cause shoot-through/shoot-thru/flow through when the switch in question has a short. In an MDDCP, this effect can further amplify the voltage ripple, which can, in turn, be detrimental to the converter. One approach to

This is the gameplay of black mist-like game, where only the target of attack would be disabled for some time. The player would have to collect the necessary items to recover the whole team. (No sound at this stage. You can still configure the audio components afterwards) A: Here's my technical answer (based on the developer's post): Music, sound effects, and other audio components have a single track, and cannot be split. If you need

---

to split a single track into sub-tracks, you can do that yourself, using an editing software such as FruityLoops. After that, you can have the software run your multiple tracks through an audio mixers (e.g. Ableton, using UnkleAudio) and send them to your sound card(s) using a USB audio interface. You are supposed to have the editors' output from the track sections on, and not to worry about the audio sync that the software provides; as the software is meant to be flexible with audio tracks. (on Windows, use FruityLoops, on Mac, Logic, and on Linux, Audacity) What to do first: Make the audio track on the editor's default settings (e.g. 4'33"). Then, in the audio mixers, make sure you have the the editor's file as reference for the track. Bring that track's output to your line-in, and make sure the editor's input and the line-in are both active. Split it (see the software's instruction if needed), so you'll have one track that has all the vocals and a different track that has all the music, drum, etc.
