By combining research tools, teaching facilities and outreach programs, it will eventually become a regional center for biodiversity science. Though the sciences have long been intertwined, it is only recently that the connection has been so well characterized. Scientists have identified a new pattern in the evolution of plants and animals, tracing it to a quiet revolution in evolutionary thinking some three centuries ago. The pattern connects physical, chemical, and evolutionary biology, thereby solidifying the longstanding integration of studies across different disciplines. Some of the work describing this pattern – evolution of reduced developmental barriers (EDB) – has been widely accepted within the scientific community. But, that science has only highlighted how little we know about the evolutionary processes that underlie what we are calling EDB. What are “reduced developmental barriers?” The patterns of evolution apparent in EDB are not new – they have been observed in the fossil record, and in recent experiments with modern animals – but recent work has uncovered and defined new mechanisms that underlie the evolution of EDB. For example, many insects have evolved to feed on flowers, and flowers have evolved to improve suitability for insect pollination, which are key to the survival of plants. This interaction results in traits that benefit both insects and plants. But since insect feeding and pollen selection are both essential to plant reproductive success, selection is working on them simultaneously. c6a93da74d
